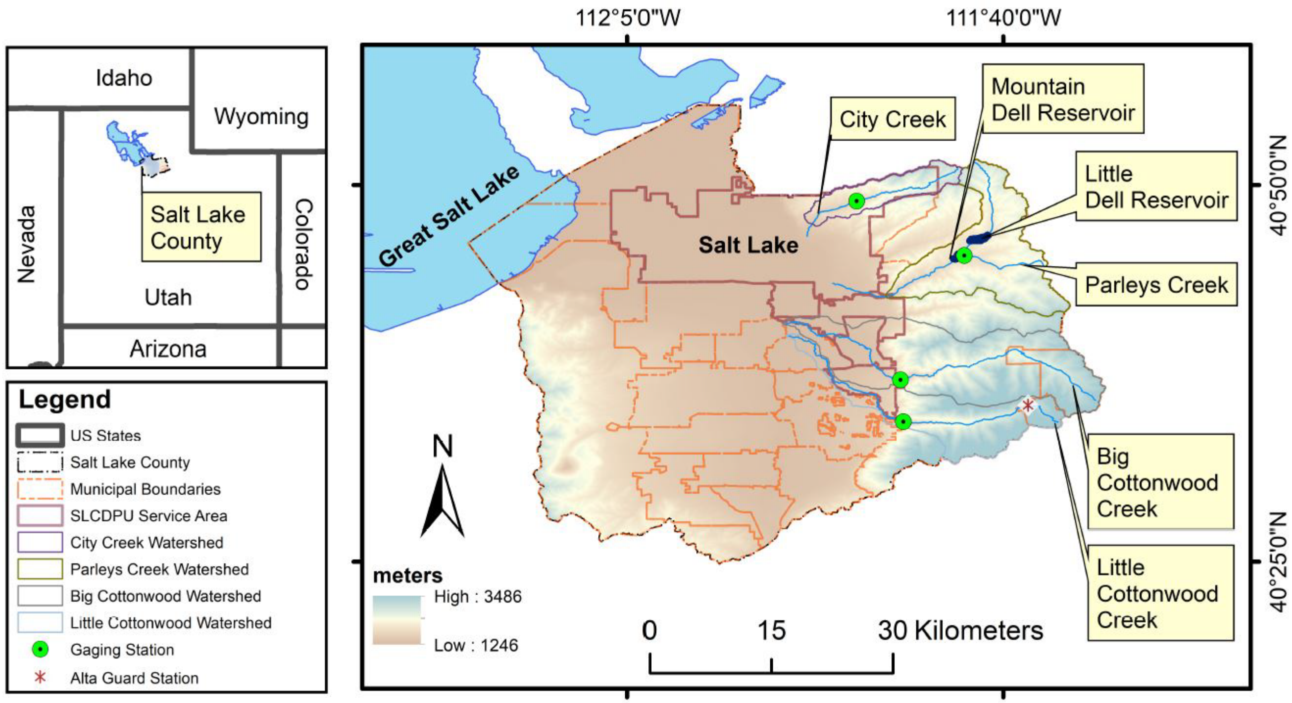
Urban Water System Modeling

Urban Water System Modeling

- ML to model water demand
- Climate influences on water system performance
- ML for water system modeling

Objective: Advance the science in water system planning in a dynamic and arid climate.



whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

ML to estimate water demand

Research Question: Can machine learning and feature engineering produce measurable improvements in water demand estimates compared to traditional methods?

Objective: Identify indicators/drivers of season-to-season and year-to-year variability in water demand, and integrate them in machine learning workflows to improve prediction skill.

ML to estimate water demand

Methods:
- Developed multiple ML algorithms
- Monthly precipitation and temperature inputs
- Population density for change over time

Results:
- 35% reduction in error during drought conditions
- All ML models display greater skill than conventional methods

Impact:
- 1st demonstration of ML for seasonal water demand estimation
- ML can improve seasonal water demand estimates
- Created operational tools for SLCDPU

Machine Learning for Water System Modeling

Research Question: Many utilities do not have the resources or personnel to develop a representative water system model to support planning and management activities. Can machine learning accurately model water system interactions and performance across different supply and demand scenarios?

Objective: Use simulated water system data to train machine learning models to predict daily to seasonal groundwater, reservoir levels, and imported water. Compare model skill to simulated targets.

ABSTRACT

Seasonal snow-derived water is a critical component of the water supply in the mountains and downstream regions, and the accurate characterization of available water in the form of snow-water-equivalent (SWE), peak SWE, and snowmelt onset are essential inputs for water management efforts. Arising from recent advancements in artificial intelligence (AI) and machine learning (ML), we introduce a large-scale ML SWE model leveraging publicly available data sources and open-source software. The model demonstrates the application of a limited feature space in a relatively simple ML architecture without the need for process-based formulations to effectively estimate spatially continuous SWE at a daily temporal resolution. Beginning with in situ SWE measurements (i.e., SNOTEL), lidar-derived terrain features, and temporal variables, we employ localized feature engineering and optimization via gradient-boosting decision trees to identify regionally unique drivers of snowpack dynamics and use the optimal features to train regionally independent artificial neural networks to estimate regional SWE at a 1-km spatial resolution. The model results yield respectable skill in reconstructed 1-km gridded SWE magnitudes in a hindcast simulation of the 2019 water year that is independent of the training and testing data. Comparing model estimates to over 6200 observations, the model demonstrates a weighted RMSE of 15.4-cm, Kling-Gupta Efficiency metric of 0.86, and a percent bias of 0.71% across 23 snow-influenced regions in the western U.S. The model simulation produces peak SWE estimates within 10-cm for twenty of the twenty-three regions, demonstrating capability in effectively capturing regional snow accumulation processes. The demonstration of low-error ML workflows capable of providing near-real-time, spatially continuous SWE estimates at a high spatial resolution provides proof-of-concept and a foundation to effectively update snow state variables that drive water supply forecasts in snow-dominated regions.

Water Resources Management
Great Salt Lake

ABSTRACT

Accurate streamflow prediction is critical for water resources management in the western United States (US), especially in balancing the beneficial uses of multiyear reservoir carryover, ecological interests, irrigation, and recreational use. With Great Salt Lake (GSL) in Utah, US facing decreasing lake levels and potential environmental disaster, we investigate the utility of the National Water Model (NWM) as a water resources management tool. Using the NWM retrospective v2.1 simulations and comparing daily and seasonal flow volumes to 48 USGS gauge stations, the NWM demonstrated decreasing model performance at locations closer to the GSL where there is extensive water resources infrastructure. Given the reaches closest to the GSL are critical for lake-level management, we explored XGBoost, Random Forest, Long Short-Term Memory, and Convolutional Neural Network Machine Learning (ML) algorithms to post-process the outputs of the NWM to account for the impacts of large-scale water resources infrastructure. Using upstream reservoir storage percentage of full capacity, the seasonality index, Snow Telemetry (SNOTEL) snow water equivalent (SWE) catchment observations, and NWM outputs as inputs into the ML pipeline, we observed significant improvement in the estimated daily flow (cms) and seasonal accumulated flow volumes (mm3). The overall Kling-Gupta Efficiency (KGE), Nash–Sutcliffe (NSE), Percent Bias (PBIAS), and Root Mean Square Error (RMSE) for the GSL basin increased by x, y, and z, respectively. The results of the study demonstrate that water resources infrastructure may be the single greatest challenge in hydrological modeling, being the dominant regional hydrological process, and novel ML methods can account for the impacts of the infrastructure on regional streamflow without explicitly adding infrastructure rulesets.

NWM-ML Post Processing:

- Accounts for reservoir operations w/o explicit p
- Works in controlled and natural basins
- ML “learns” hydrological processes
- Monthly to Annual flow estimates
- Leverages NWM-Retrospective products (flow + climate)

Advancing Snow Observation Systems to Improve Operational Streamflow Prediction Capabilities

Problem: *In situ* snow monitoring infrastructure has proven valuable but exhibits limitations for hydrologic models in because of the spatial heterogeneity of snow distribution.

Research Activities

- Develop and adapt snow survey optimization ML algorithm to identify the optimal sensor deployment locations
- Develop a low-cost low-power snow sensing system network (w/communications) based on open-source firmware (e.g. Arduino IDE)
- Create catchment snow-off and snow-on datasets using UAV (Structure-for-motion & LiDAR)

Teaching Goals, Philosophy, and Ideas

whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

Teaching Goals

Capable, **confident**, and **successful** students are the product of a University.

1. Intrinsic motivation to learn
2. Fundamental Positive Action principles into students' cognitive, affective, and behavioral learning domains
3. Enhance critical thinking and analytic skills
4. Foster student development and personal growth
5. Be a role model

whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

Teaching Goals

Department of
Civil & Environmental Engineering
THE UNIVERSITY OF UTAH

- Develop a lifelong love of learning
- Apply principles, concepts, theories, and generalizations to new problems and situations
- Analytic and problem-solving skills
- Draw reasonable inferences from observations
- Synthesize and integrate information and ideas
- Think holistically: to see the whole as well as the parts
- Think creatively
- Enhance concentration, listening, speaking and writing skills

- Develop appropriate study skills, strategies, and habits
- Learn techniques and methods used to gain new knowledge
- Informed understanding of the role of science and technology
- work productively with others
- Grow management and leadership skills
- Commitment to organization, efficiency, skillful, and accurate work
- Improve ability to follow directions, instructions, and plans
- Commitment to personal achievement
- Improve self-esteem/self-confidence

whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

Motivation to Teach and Teaching Philosophy

Fundamentals of success learning

- Diagnose problems (topic knowledge)
- Formulate solutions (hypothesis)
- Execute a plan (methodology)
- Face adversity and critically evaluate
- Be confident

Philosophy

- Inspire
- Strive for excellence
- Nurture critical thinking
- Passion for the learner
- Empathy
- Strong work ethic
- Treat everyone with respect and as friends

whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

Teaching Philosophy

Creating a stimulating learning environment

- Interactive lectures
- Thought provoking activities
- Active learning examples and demonstrations
- Creative and collaborative working sessions
- Project-based learning

Engaging classroom experience

- Defined learning objectives
- Frequent assessments to identify gaps in student learning
- Encourage questions
- Share views, ideas, challenges
- Peer learning and shared experiences

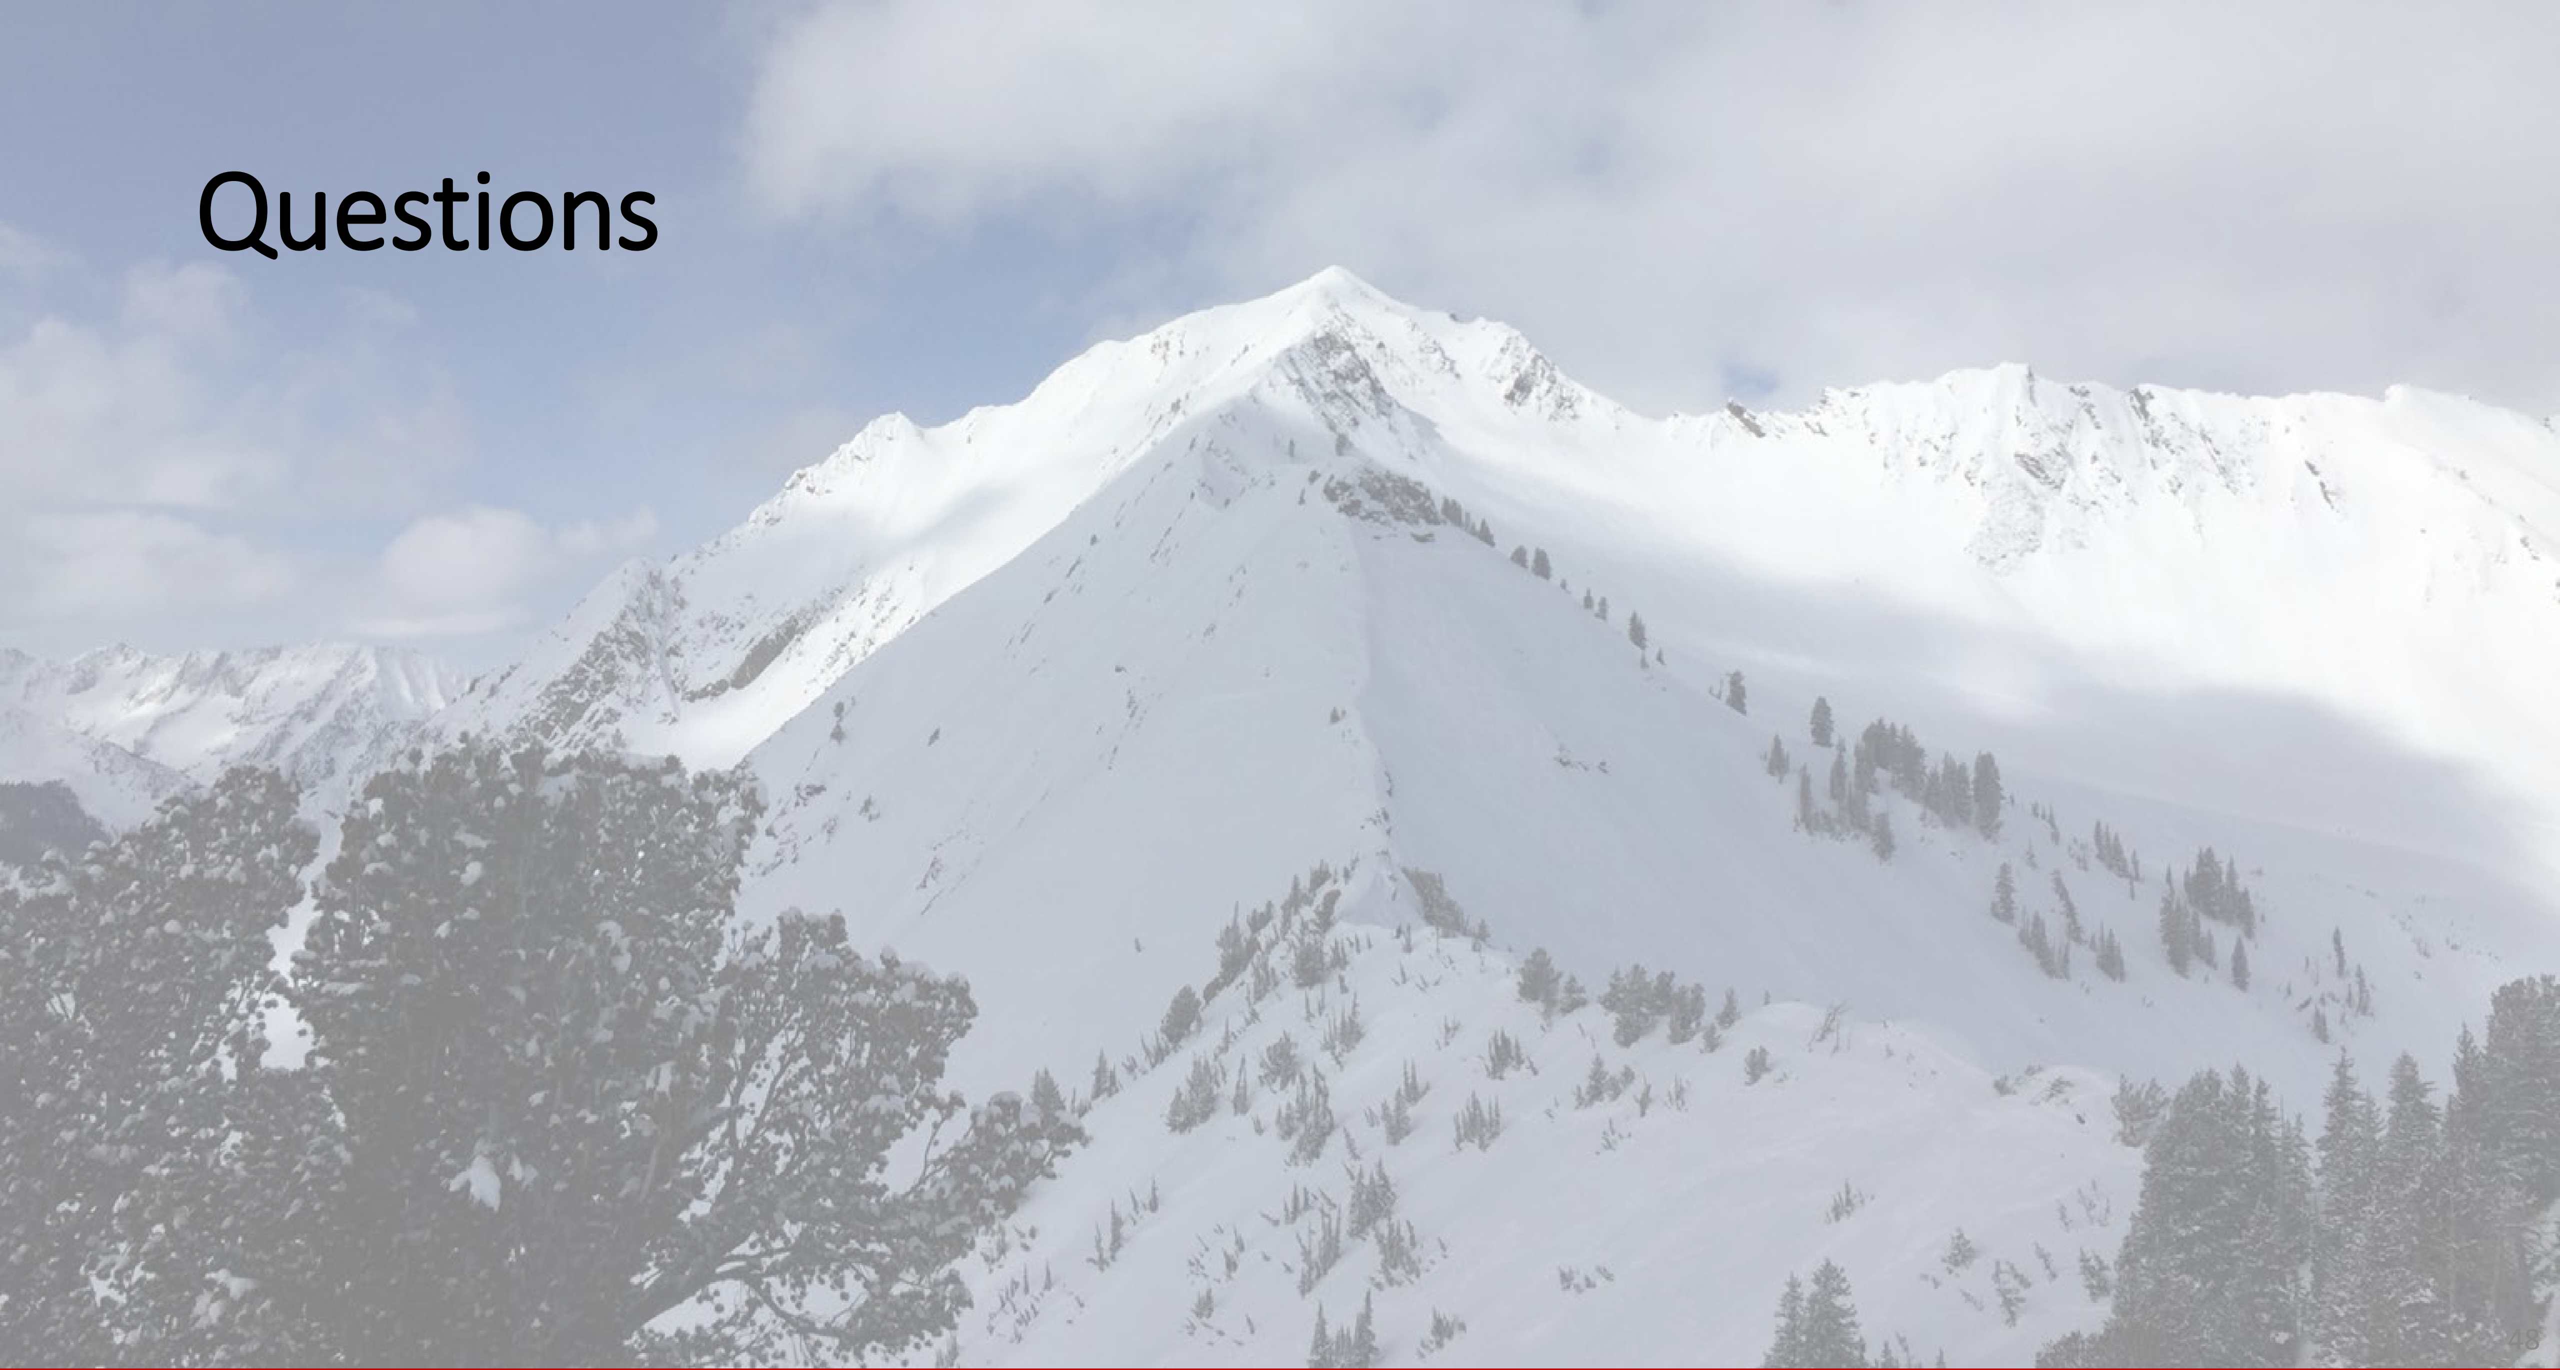
Questions



whitelightning450 ryan-johnson-022a8784 rjohnson18@ua.edu

Aliso Creek Water Quality

- Water quality (nitrates) increased in the urban water system, likely from landscaping runoff.
- Water quality improved as the stream traveled through natural riparian habitat (Aliso Wilderness Park).
- Water treatment facility effluent reduced water quality.
- Golf course reduced water quality.
- Beach closures due to poor water quality.

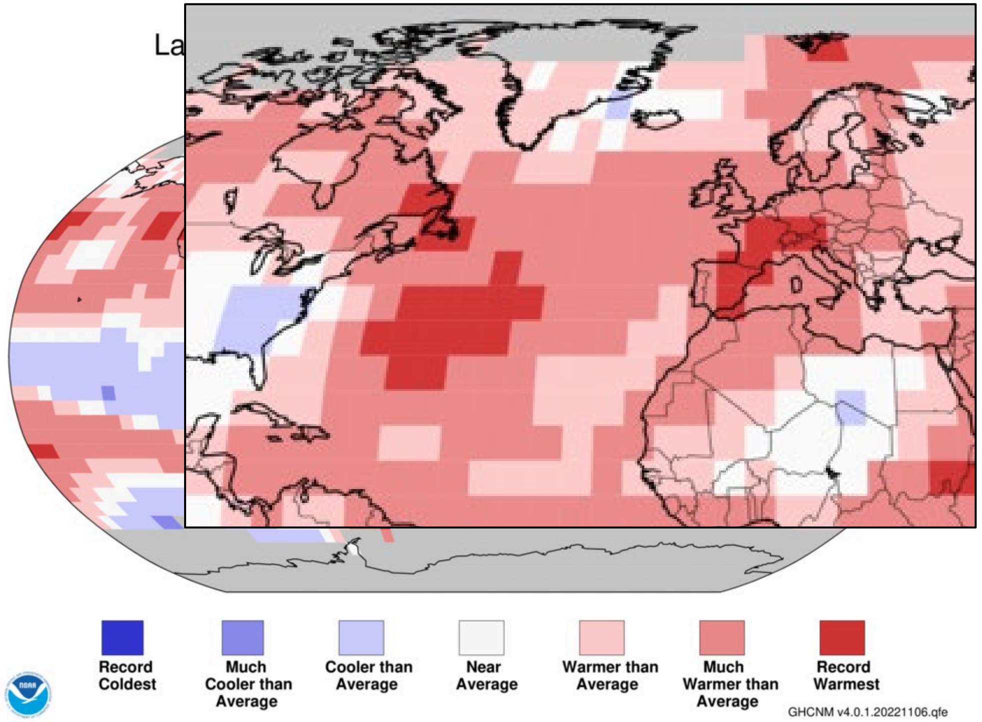
Precipitation Estimates (October)

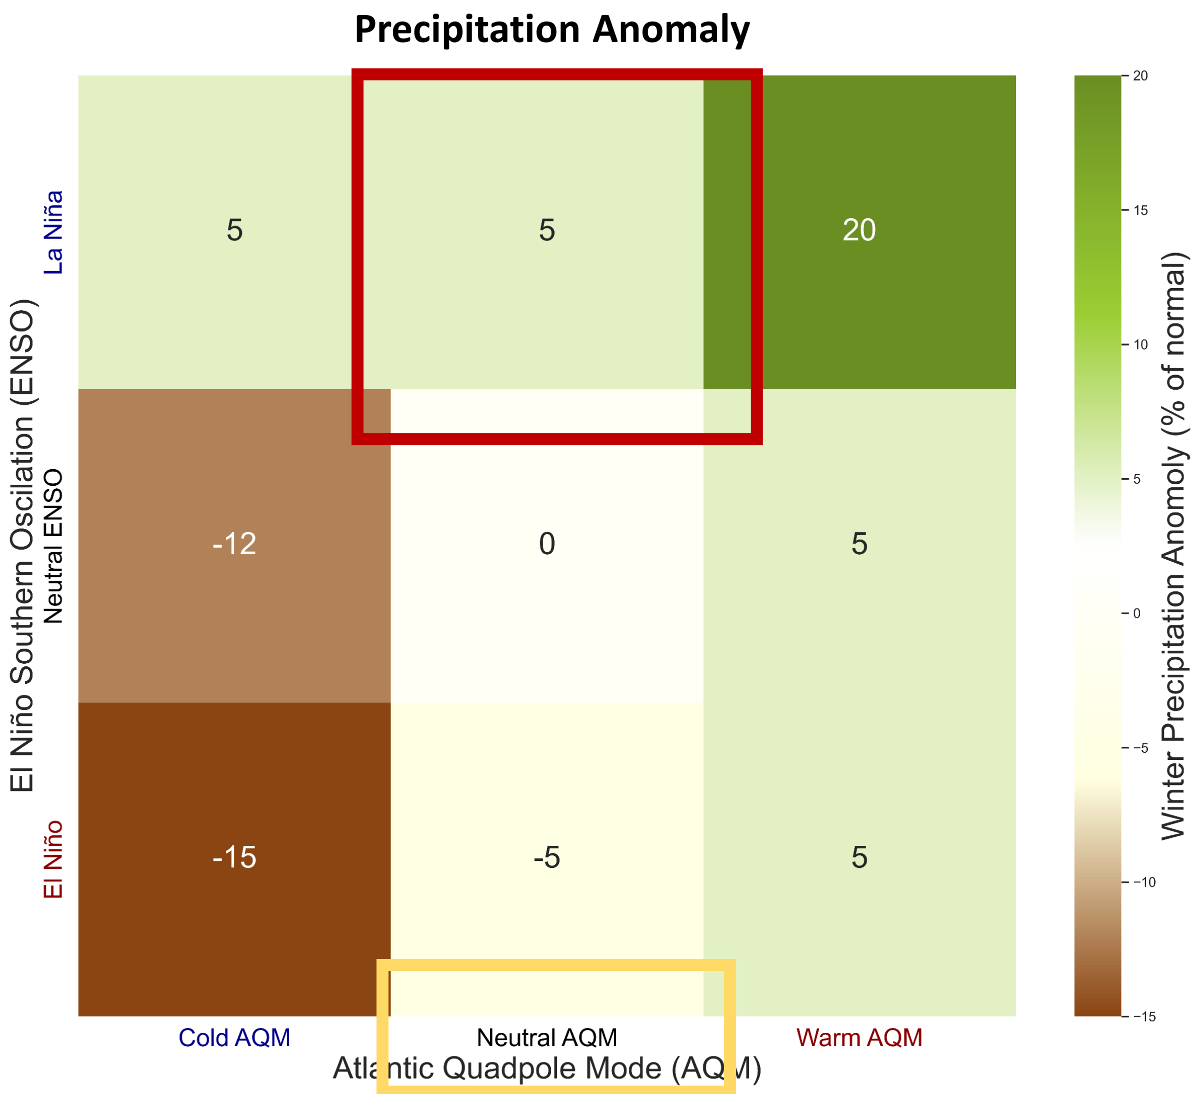
CURRENT STATUS:

LA NIÑA ADVISORY

OCTOBER 13, 2022

Forecasts indicate a 75 percent chance that La Niña—the cool phase of the ENSO climate pattern—will persist across the tropical Pacific for the third winter in a row. The map at left shows the broad swath of cooler-than-average water (blue) across the Pacific at the equator, one of the hallmarks of La Niña. Scroll down to learn about La Niña's influence on global and U.S. seasonal climate.

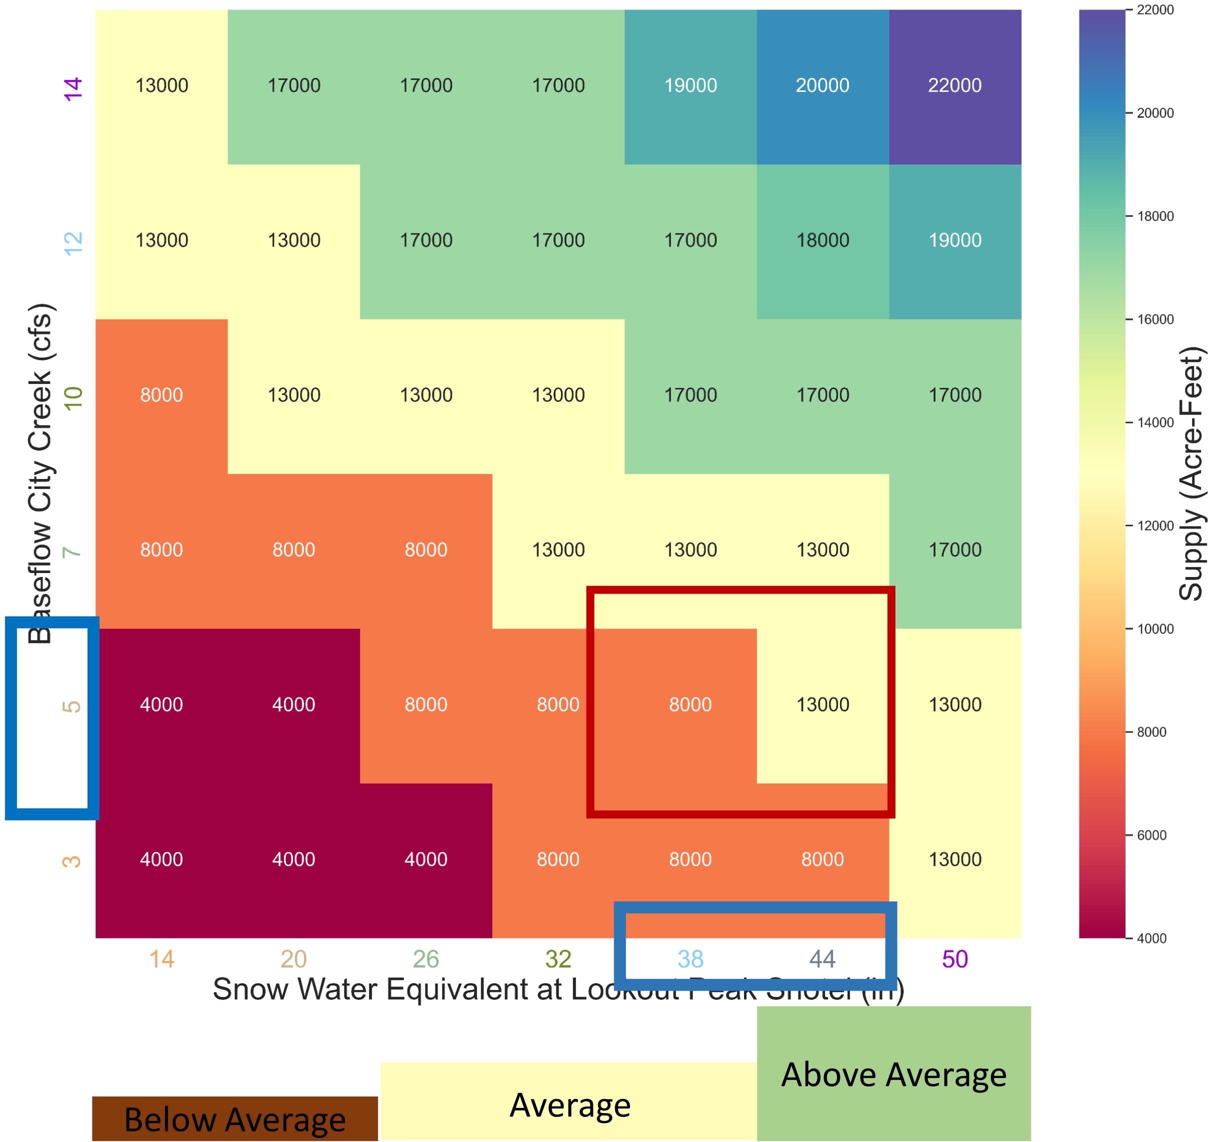




Surface Supply Yield (February)

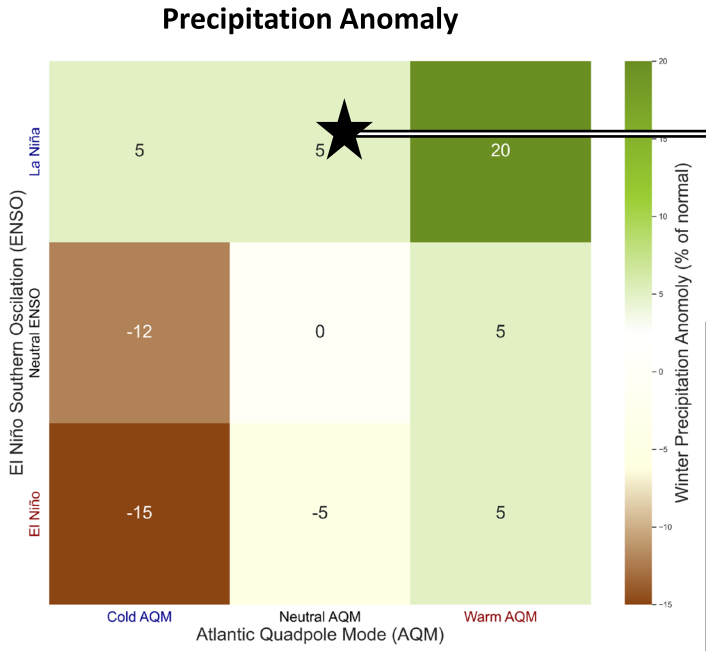
- Use precipitation prediction to determine total max SWE.
- Average annual winter baseflow.
- Reduce uncertainty in supply. estimate.

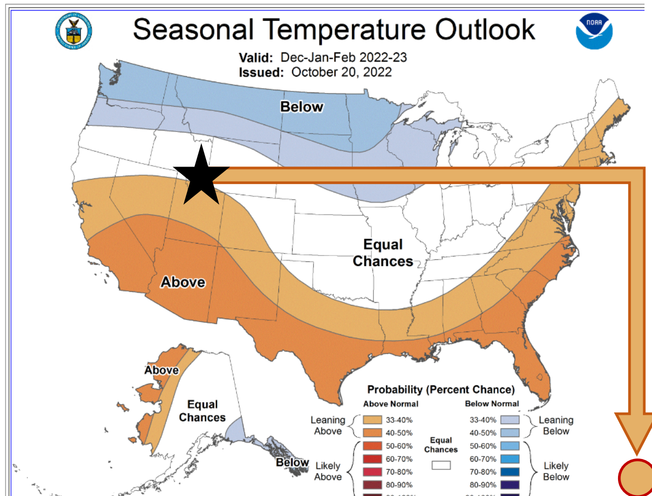
Expected Streamflow

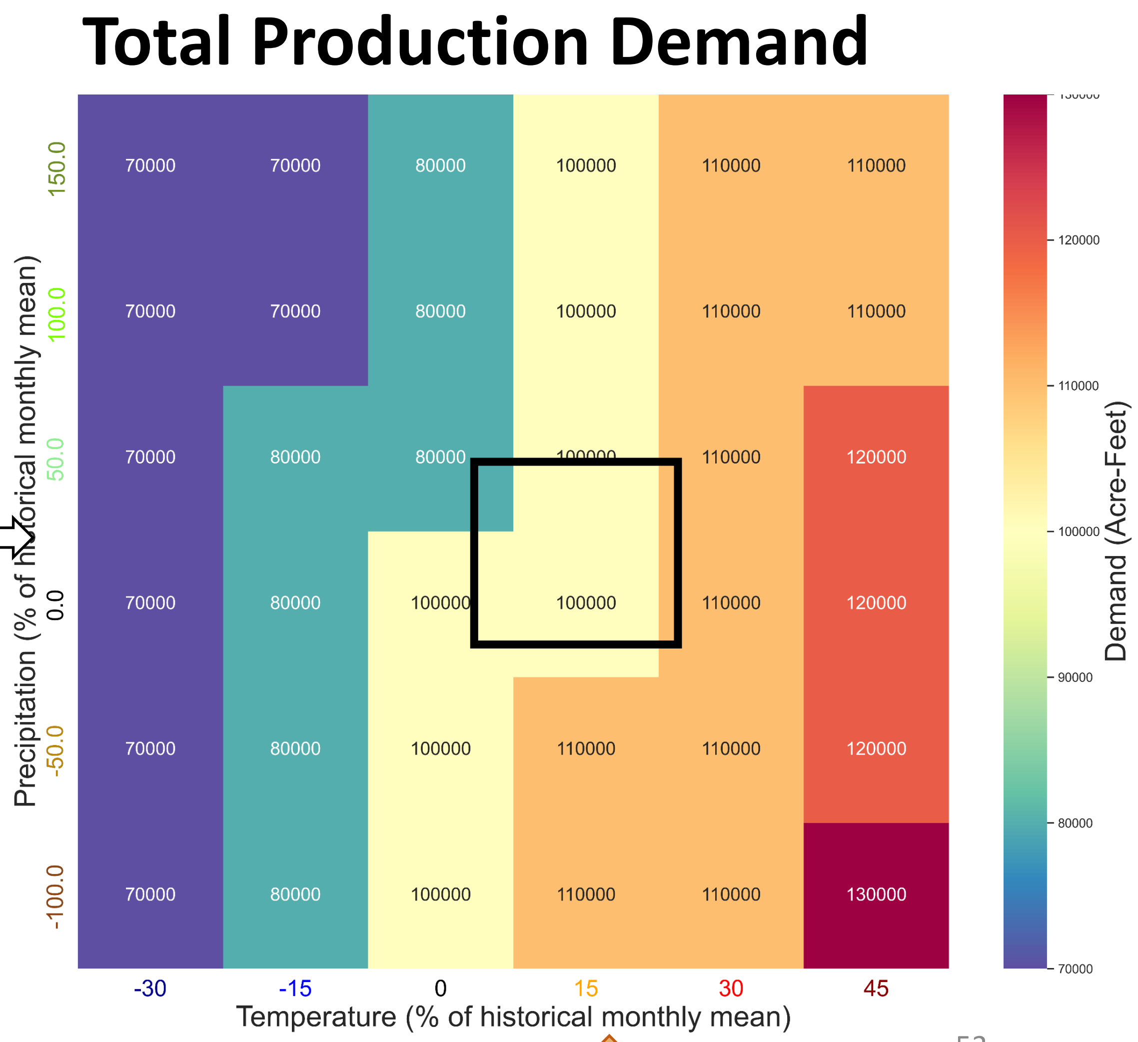


Municipal Demand Estimates (February - April)

Use climate prediction (e.g., spring NOAA outlook and/or Climate Matrix) to determine expected monthly temperature and precipitation







Water System Performance (February - April)

- Using supply tools, estimate 120,000 to 160,000 acre-feet.
- From NOAA climate outlook, demand should range between 80,000 to 110,000 acre-feet (mean 100,000 acre-feet).
- Estimated Deer Creek needs: 10,000 to 40,000 acre-feet.

Advancing Research in Geosciences using AI/ML

Summary: Connections with snow and streamflow AI/ML methods to advance the understanding of geosciences using AI/ML methods.
- Advance core geosciences program goals and use AI/ML methods for addressing scientific problems. Build the capacity of AI/ML to explore and/or emulate physically based models.

Core geoscience goal: Advance the representation of snow on the earth's surface to support water supply forecasting and explore the impacts of a changing climate.

Broader impacts: developing AI/ML training datasets, python-based tools (evaluation), open source software, supporting workforce development. Supporting the greater hydro-meteorological practioning and research community.

Environmental Engineering

Summary: Investigation of a no-snow future within the western US, beginning with the Great Salt Lake using SNOTEL to investigate precipitation phase during the snow season (October to July).

Research questions: how has precipitation phase changed in the past half century and what can we expect in a changing climate in montane, high elevation watersheds. Most studies relate a no snow future to the impacts of temperature on snow melt, investigation peak SWE and the duration of snow. However, snowmelt is primarily driven by the energy from SW radiation.

Applications benefits: connect newfound knowledge related to precipitation phase (or at least the temperature when precip is occurring) to naturalized and managed water systems. How much snow can we expect to occur in the future and relate it to the quantity of melt to fill reservoirs/GW recharge,

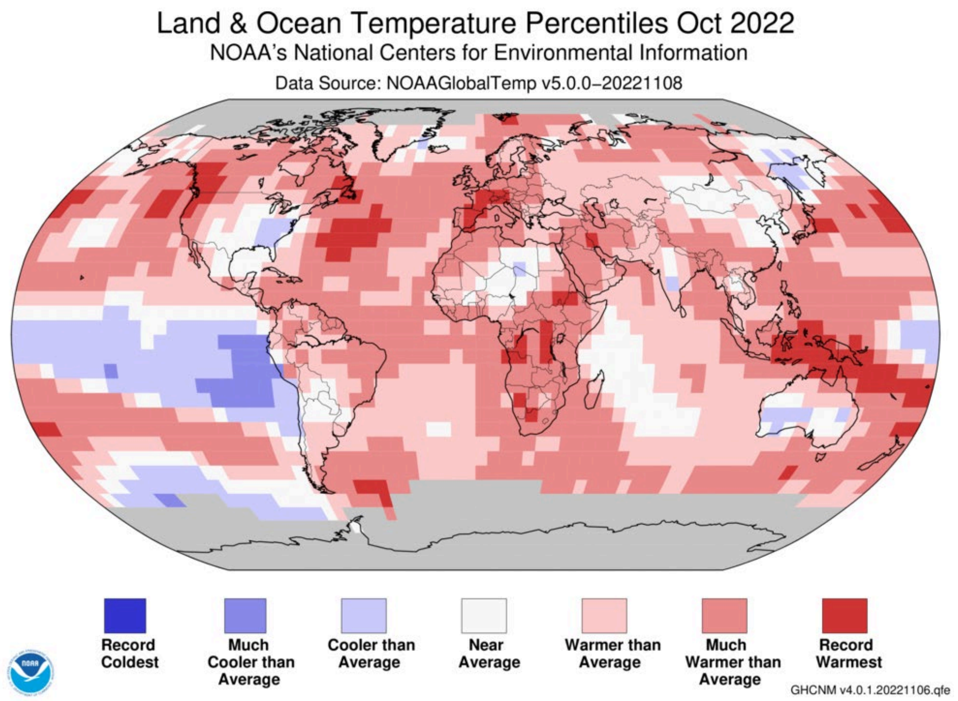
Environmental Sustainability: GSL sustainability, no snow future, climate change/scenarios/impact of scenarios on water resources management.

NIDIS: future drought risk across the West and in the context of a changing climate

- Drought vulnerability assessments
- Developing drought plans and communication plans
- Identifying primary drought impacts
- Optimal drought indicators and/or triggers and improving monitoring
- Developing drought dashboards with relevant tools and information and demonstrating the application of drought data to enhance decision-making

CVP – Advancing the Understanding of multi-year to decadal climate variability and predictability for US climate predictions

- Data analysis and investigation focused on mechanisms that govern the variability of the coupled climate systems and its predictability on the multi-year to decadal timescale with long-term observation data and or model data.
- Investigation of the relationship between the Atlantic meridional overturning circulation (AMOC) and impacts on the cryosphere and hydroclimate in the Western US



Positive Action Principles

1. Positive actions for your mind
2. Responsible self-management
3. Continuous Improvement
